

**ABSTRACT**

The mobile communication terminal uses a battery as a power source. The mobile communication terminal includes a detector 103, a decision section 105, a transmission-reserved controller 105, 107, and a reserved data transmission controller 105, 107. The detector 103 detects the voltage of the battery acting as a power source. The decision section 105 decides a difference relationship between a voltage level detected by the detector and a prescribed value. The transmission-reserved mail controller 105, 107 stores transmission data as transmission-reserved data into a storage, without starting the transmission operation, when the decision section decides that the detected voltage level is less than the prescribed value, in response to a data transmission request and then maintains its wait state. The reserved data transmission controller 105, 107 radio-transmits the transmission-reserved data to be stored in the storage when the decision section decides that the detected voltage level exceeds the prescribed value after maintenance of the wait state.
